Abstract: I describe the model of binary asteroid for simulating long-period component of lightcurve with occultation and/or eclipse events. There is assumed a spherical shape for both components and an elliptical orbit of the secondary. With this model, I obtained possible ranges of secondary’s orbital parameters and its size (secondary-to-primary size ratio $R_s/R_p$, sidereal orbital period $P_2$, semimajor axis $a/R_p$, ecliptical coordinates of the orbit’s normal $\lambda_n$ and $\beta_n$, eccentricity $e$, and length of pericenter $\omega$) for two near-Earth asteroids: 1991 VH and 1996 FG$_3$. The parameters are estimated analytically from observed features in the lightcurve at first and then improved by numerical modelling. Possible ranges of the parameters in the best solution for asteroid 1991 VH are: $R_s/R_p = 0.37$–0.44, $P_2 = (1.3589$–$1.3600)$ d, $a/R_p = 4.65$–5.68, $\lambda_n = 15^\circ$–185$^\circ$, $\beta_n = 46^\circ$–86$^\circ$, $e = 0.043$–0.060, $\omega = 63^\circ$–94$^\circ$. For 1996 FG$_3$: $R_s/R_p = 0.27$–0.32, $P_2 = (0.6725$–$0.6728)$ d, $a/R_p = 2.98$–3.48, $\lambda_n = 176^\circ$–331$^\circ$, $\beta_n = 87^\circ$–58$^\circ$, $e = 0.005$–0.026, $\omega = 21^\circ$–344$^\circ$. For both asteroids, there are other solutions which simulate the lightcurves almost equally well.
